## **Constant folding**

Compiler optimization and exercise of AST modification

## **Notes**

- The idea is trying to evaluate constant expressions in a compile-time as oppose to run-time **when** we have all things we need to evaluate it.
- For example given var i : Int = 3 \* 4 + 2; . We should be able to replace i 's RHS expression with "14".
- Remember AST is immutable so we need to return a new AST

## How to accomplish it?

Using visistor pattern and modifying the AST by returning a updated node

## Lab assignment

We are trying to use a inherited and synthesized attribute to achieve this.
